

TEAM ONBOARDING — Join the Shared Claude Brain

How to get set up, and why this makes all of us better · June 2026

What this is, in one paragraph

Our team runs a shared playbook file (CLAUDE.md) in a private GitHub repo. When you open Claude in that folder, your Claude instantly knows everything the team has learned: the rules we paid for in real money, the findings that were verified across multiple members' data, and every lesson anyone's Claude has logged. When YOUR Claude learns something new, it gets written into the same file and shared back. One team, one memory — every mistake only has to be paid for once, by one of us, ever.

STEP 1 — Create a GitHub account (5 min, free)

1. Go to github.com/signup
2. Enter your email, create a password, pick a username (this username is your team identity — keep it sensible)
3. Verify the email they send you. Free plan is all you need.

STEP 2 — Send your username to the team lead

Message your GitHub **username** (not your password — never your password, nobody on the team will ever ask for it) to the team lead. You'll receive an email invitation to a private repository. Open it and click **Accept invitation**. Until you accept, the repo link shows you a 404 — that's normal.

STEP 3 — Install the tools (10 min)

1. **Claude Code**: claude.com/claude-code — install for your OS and log in with your Claude account.
2. **Git**: Mac — open Terminal, type `git --version`, accept the install prompt if one appears. Windows — install from git-scm.com (default options are fine).

STEP 4 — Clone the repo and set up your local file

```
# in Terminal:
git clone https://github.com/Ghinsinc/<REPO-NAME>.git
cd <REPO-NAME>
cp my-bot.example.md my-bot.md      # then edit my-bot.md with YOUR details
```

my-bot.md is yours alone. It holds your server/paths/limits and is gitignored — it never uploads, the team never sees it. This is how we share a brain without sharing anyone's keys. Matching rule: **never commit keys, wallets, seed phrases, or server IPs to the repo.** If you're unsure whether something is safe to commit, it isn't.

STEP 5 — Start working with the team brain

```
cd <REPO-NAME>
git pull      # get the team's latest lessons (do this before every session)
claude       # open Claude IN this folder — it reads CLAUDE.md automatically
```

Try the shared commands (type `/` to see them — e.g. a health check command). When your Claude learns a lesson worth sharing, tell it: "add this to the team CLAUDE.md lessons and push." It handles the git for you.

Why this makes the whole project better

Without the shared brain	With it
Each member repeats the same expensive mistakes	A mistake is paid for ONCE, then it's a written rule for everyone
One person's "discovery" might be luck/noise	Findings only count after they replicate on 2+ members' data — N books beat 1
Everyone prompts their Claude from scratch	Every Claude starts with the full team playbook + shared commands
Knowledge lives in chat histories and leaves when people do	Knowledge compounds in one versioned file, forever
Copying a teammate's exact setup/patch breaks things	Findings travel as evidence + writeups; you re-validate on your own data first

House rules (the short version)

- 1. Pull before you work; push lessons when you learn them.
- 2. Evidence or it didn't happen — claims ship with the query/data that produced them.
- 3. Nothing deploys to a live system without validating on your own data first.
- 4. No secrets in the repo, ever. Your private details live in my-bot.md (local only).
- 5. Don't rewrite others' lesson entries — append yours, dated and initialed.
